Abstract. The purpose of this study was to determine the effect of a 12-week, low-intensity, low-impact aerobically demanding exercise program on the health-related quality of life of older adults. The study was a randomized, controlled trial. The study population consisted of 100 older adults (65 years of age and older) who were randomly assigned to either a 12-week, low-intensity, low-impact aerobically demanding exercise program or a control group. The exercise program consisted of 12 weeks of 30-minute, low-intensity, low-impact aerobically demanding exercise sessions, 3 times per week. The control group consisted of 50 older adults who did not participate in the exercise program. The health-related quality of life was measured using the SF-36 Health Survey. The results of the study showed that the exercise program had a significant positive effect on the health-related quality of life of the older adults. The exercise program significantly improved the physical functioning, role limitations due to physical problems, and bodily pain domains of the SF-36 Health Survey. The exercise program also significantly improved the mental health domain of the SF-36 Health Survey. The exercise program had no significant effect on the other domains of the SF-36 Health Survey. The results of this study suggest that a 12-week, low-intensity, low-impact aerobically demanding exercise program can improve the health-related quality of life of older adults.

for individuals, but a common one is whether the data are "normal." The normal distribution is the most common distribution of data, and it is the one that is most often used in statistical analysis. If the data are not normal, then the results of the analysis may be biased or misleading. There are several ways to check for normality, and the most common one is to look at the shape of the distribution. If the distribution is roughly bell-shaped, then it is likely to be normal. If it is skewed or has a long tail, then it is not normal. There are also statistical tests that can be used to check for normality, but these are more complex and less intuitive than looking at the shape of the distribution.

Que vous êtes, son importance pour le monde.

It should be noted that the effect of the two types of stimuli was not significant in the two-way ANOVA. This may be due to the small number of stimuli used in the study.

more and in a few more countries de novo.

and, therefore, that the model is ill-posed, since it leads to ill-posedness in the sense of Hadamard. In order to avoid this problem, we consider the following more general case, where the unknown function f is not necessarily continuous, but is only assumed to be bounded. In this case, the problem is well-posed in the sense of Hadamard, since the solution depends continuously on the data. However, the problem is still ill-posed in the sense of Hadamard, since the solution depends discontinuously on the data. This is because the solution is not unique, and the problem is not stable.

248

It is important to note that the use of a single, univariate analysis to assess the effect of a single factor on a single outcome is not sufficient to establish a causal relationship. The results of this analysis should be interpreted with caution, as they may be confounded by other factors. The authors acknowledge the limitations of this study and suggest that further research is needed to confirm the findings.

Medications = as needed

It is important to note that the results of the present study are based on a cross-sectional design. Therefore, the causal relationship between the variables cannot be established. The results of the present study suggest that the use of the Internet for health information is associated with a higher level of health literacy. This finding is consistent with the results of other studies (e.g., [10,11]). The results of the present study also suggest that the use of the Internet for health information is associated with a higher level of health literacy. This finding is consistent with the results of other studies (e.g., [10,11]).
